1 VGFFMC

Program to use the F-field formalizm to solve the scattering problem for a particle of arbitrary shape. The particle is divided into an array of dipoles on a cubic lattice (by program VGFIN). The scattering is computed through a plane wave expansion of the field inside the particle. From this the external field and phase function are calculated (in program VGFPHZ)

1.0.1 Units:

All equations are in Gausian units. Lengths are all relative, that is, if you input a wavelength of 10 um then all other lengths must be in um. You may use m or cm or furlongs if you wish as long as all lengths are in the same units.

1.0.2 Time dependence:

The VGF code uses the time dependence $e^{-iwt)}$.

1.0.3 Geometry:

The particle is aligned with it's symmetry axis along the Z-axis. The incident plane wave may be rotated around the particle by the angles alpha, beta, and gamma (corresponding to the Euler angles as given in Arfkin, Mathematical Methods for Physicists, 3nd Ed., Academic Press, NY, 1970). All calculations are done in this 'body frame.' The polarization is given relative to the x-axis in the lab or global frame. In this frame the incident plane wave traveles in the z-hat direction and the polarization is in the x-y plane. The direction of the electric field is measured by an angle psi from the x-axis.

1.1 Algorithm

We will assume a field with complex time dependance.

$$\mathbf{E}\left(\mathbf{r},t\right)=\mathbf{E}(\mathbf{r})\exp(-i\omega t)+c.c. \tag{1}$$

and with a Green's function solution

$$\mathbf{E}(\mathbf{r})(1+\frac{4\pi}{3}\chi)=\mathbf{E}^{e}(\mathbf{r})+\int d^{3}\mathbf{r}'\mathbf{G}\left(\mathbf{r},\mathbf{r}'\right)\cdot\chi(\mathbf{r}')\mathbf{E}(\mathbf{r}') \tag{2}$$

We define the term

$$W\left(\mathbf{r}\right)=\frac{\chi(\mathbf{r})}{(1+\frac{4\pi}{3}\chi(\mathbf{r}))} \tag{3}$$

then letting

$$\mathbf{F}(\mathbf{r})=\mathbf{E}(\mathbf{r})(1+\frac{4\pi}{3}\chi)$$

and the F-field

$$\mathbf{F}(\mathbf{r})=\mathbf{E}^{e}(\mathbf{r})+\int d^{3}\mathbf{r}'\mathbf{G}\left(\mathbf{r},\mathbf{r}'\right)\cdot W\left(\mathbf{r}'\right)\mathbf{F}(\mathbf{r}') \tag{4}$$

to make our calculations more compact.

We can write the F-field as

$$F_{\mu i}=E_{\mu i}^{in}+\sum_{\nu}G_{\mu i\nu j}W_{\nu}F_{\nu j} \tag{5}$$

where, for convenience, the cell dimension d_{μ}^{3} is included in the W term.

$$W_{\nu}=Wd_{\nu}^{3} \tag{6}$$

Symbolically, this may be written as

$$\mathbf{F}=\mathbf{E}^{in}+\mathbf{GWF} \tag{7}$$

Proceeding directly to a numerical solution at this point would be equivalent to the DGF. Instead, we are going to try a variational solution. First, an error term $\boldsymbol{\varepsilon}$ is defined such that

$$\boldsymbol{\varepsilon}=\mathbf{F}-\mathbf{E}^{in}-\mathbf{GWF} \tag{8}$$

Writing components yields

$$\varepsilon_{\alpha i}=\sum_{\beta}\sum_{j}\left(1_{\alpha i\beta j}-G_{\alpha i\beta j}W_{\beta}\right)F_{\beta j}-E_{\alpha i}^{in} \tag{9}$$

Here the factor

$$F_{\alpha i}^{st}=-W_{\alpha}G_{\alpha i\alpha j}F_{\alpha j} \tag{10}$$

is the specially defined self term discussed below as the "self term." Note that

$$1_{\alpha i\beta j} = \delta_{\alpha\beta}\delta_{ij} \tag{11}$$

Equation (61), gives a definition of the diagonal elements of the dyadic Green function taken from the self term,

$$F^{st}_{\alpha i} = \delta_{\alpha\beta}\left(\frac{4\pi}{3}\Gamma_\alpha\right) W_\alpha F_{\alpha i} \tag{12}$$

Equation (**??**) gives a discretized form of the dyadic Green function diagonal terms.

$$G_{\alpha i\alpha j} = \frac{4\pi}{3d^3_\alpha}\Gamma_\alpha\delta_{ij} \tag{13}$$

Now, for convenience, define the quantity

$$M_{\alpha i\beta j} = (1_{\alpha i\beta j} - W_\beta G_{\alpha i\beta j}) \tag{14}$$

where the α, i, β,and j are not summed over. Then

$$\varepsilon_{\alpha i} = M_{\alpha i\beta j}F_{\beta j} - E^o_{\alpha i} \tag{15}$$

where in equation (15) the summation convention has been employed throughout, on both Latin and Greek indices.

The function Φ to extremize is defined as the squared magnitude of the error $\boldsymbol{\varepsilon}$,

$$\Phi = \boldsymbol{\varepsilon}_{\alpha i}\boldsymbol{\varepsilon}^*_{\alpha i} = F_{\beta j}M^T_{\beta j\alpha i}M^*_{\alpha i\gamma l}F^*_{\gamma l} - E^{o*}_{\alpha i}M_{\alpha i\beta j}F_{\beta j} - E^o_{\alpha i}M^*_{\alpha i\beta j}F^*_{\beta j} + E^o_{\alpha i}E^{o*}_{\alpha i} \tag{16}$$

Again for convenience two additional quantities are defined which will shorten the notation

$$K_{\gamma l\beta j} = M^{*T}_{\gamma l\alpha i}M_{\alpha i\beta j} \tag{17}$$

$$X^*_{\beta j} = E^{o*}_{\alpha i}M_{\alpha i\beta j} \tag{18}$$

Then equation (16) can be written compactly as

$$\Phi = F^*_{\gamma l}K_{\gamma l\beta j}F_{\beta j} - \left[X^*_{\beta j}F_{\beta j} + X_{\beta j}F^*_{\beta j}\right] + E^o_{\alpha i}E^{o*}_{\alpha i} \tag{19}$$

Because the form of $\mathbf{F}$ is not known, a trial function $\tilde{\mathbf{F}}$ can be used which is an expansion in some basis function set $\Psi_{\beta N}$. We define the trial function $\tilde{\mathbf{F}}$ by

$$\tilde{F}_{\beta j} = \sum_{N=1}^{N_k} a_{Nj}\Psi_{\beta N} \tag{20}$$

where the sum has been written explicitly. The function $\tilde{\mathbf{F}}$ is substituted for $\mathbf{F}$. The functions $\Psi_{\beta N}$ we will assume to be of the form

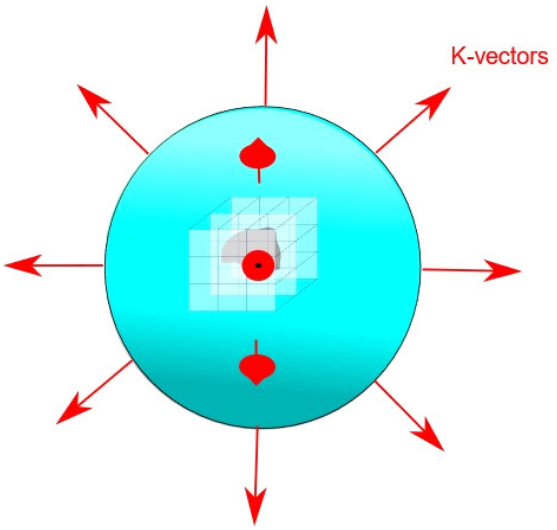

Figure 1:

$$\Psi_{\beta N} = e^{imk\hat{\mathbf{k}}_N \cdot \mathbf{r}_\beta} \tag{21}$$

which depend on the $\hat{\mathbf{k}}_N$

These are read in from a file. That file is created by vgfkv.f. And it looks like it makes a k_N in equally spaced increments in the θ and ϕ directions. Then equation (16) is approximately given by

$$\Phi = \Psi^*_{\gamma M} a^*_{Ml} K_{\gamma l \beta j} a_{Nj} \Psi_{\beta N} - \left[X^*_{\beta j} \Psi_{\beta N} a_{Nj} + X_{\beta j} \Psi^*_{\beta N} a^*_{Nj} \right] + E^o_{\alpha i} E^{o*}_{\alpha i} \tag{22}$$

Now the notation can again be simplified by defining two functions

$$H_{MlNj} = \Psi^*_{\gamma M} K_{\gamma l \beta j} \Psi_{\beta N} \tag{23}$$

$$Y^*_{Nj} = \Psi^T_{N\beta} X^*_{\beta j} \tag{24}$$

Then the final form of equation (16) is

$$\Phi = a^*_{Ml} H_{MlNj} a_{Nj} - \left[Y^*_{Nj} a_{Nj} + Y_{Nj} a^*_{Nj} \right] + E^o_{\alpha i} E^{o*}_{\alpha i} \tag{25}$$

To extremize Φ, equation (25) is differentiated with respect to a^*_{Li}, yielding

$$\frac{\partial \Phi}{\partial a^*_{Li}} = H_{LiNj} a_{Nj} - Y_{Li} \tag{26}$$

The result is set equal to zero. Equation (26) can be written in matrix form as

$$(\mathbf{H})(\mathbf{a}) = (\mathbf{Y}) \tag{27}$$

The solution for $(\mathbf{a})$ is given by

$$(\mathbf{a}) = (\mathbf{H})^{-1} (\mathbf{Y}) \tag{28}$$

Writing out the $(\mathbf{H})$and $(\mathbf{Y})$ matrix explicitly in components we have

$$\begin{aligned} H_{MlNj} &= \Psi^*_{\gamma M} \left(1_{\alpha i \gamma l} - W^*_\beta G^*_{\alpha i \gamma l}\right) \left(1_{\alpha i \beta j} - W_\beta G_{\alpha i \beta j}\right) \Psi_{\beta N} \\ Y_{Nj} &= \left(1_{\alpha i \beta j} - W_\beta G_{\alpha i \beta j}\right)^* E^o_{\alpha i} \Psi^*_{\beta N} \end{aligned} \tag{29}$$

The functions $\Psi_{\beta N}$ could be any set of functions. A simple choice for larger particles with refractive indices that are not very different from unity is a set of plane waves:

$$\Psi_{\beta N} = e^{imk\hat{\mathbf{k}}_N \cdot \mathbf{r}_\beta} \tag{30}$$

where as before m is the complex refractive index of the particle. These functions obey the correct wave equation inside the particle. The trial functions $\tilde{F}_{\beta j}$ are given by

$$\tilde{F}_{\beta j} = \sum_{N=1}^{N_k} a_{Nj} e^{imk\hat{\mathbf{k}}_N \cdot \mathbf{r}_\beta} \tag{31}$$

Again, the summation has been written explicitly. The $\hat{\mathbf{k}}_N$ or "k-vectors" must be chosen to represent the internal wave well. A "goodness of choice" criterion for the number and direction of the $\hat{\mathbf{k}}_N$ vectors results from evaluating Φ explicitly. Observing the values of the a_{Nj} can determine which of the k-vectors are not contributing well. If the magnitude of an a_N is small, then the $\hat{\mathbf{k}}_N$ is not well placed or may not be needed.

For the sake of computation, a temporary variable is employed in the calculations that follow.

$$T_{\alpha i N j} = \sum_\beta \left(1_{\alpha i \beta j} - G_{\alpha i \beta j} W_\beta\right) \Psi_{\beta N} \tag{32}$$

Using $T_{\alpha i N j}$, H_{MlNj} and Y_{Nj} can be expressed as

$$\begin{aligned} H_{MlNj} &= \sum_\alpha \sum_i T^*_{\alpha i M l} T_{\alpha i N j} \\ Y_{Nj} &= \sum_\alpha \sum_i T^*_{\alpha i N j} E^o_{\alpha i} \end{aligned} \tag{33}$$

This is the form of the quantities used in the actual algorithms.

Then since we foudn the a_{Nj} with the matrix inversion we can calculate the

$$\tilde{F}_{\beta j} = \sum_{N=1}^{N_k} a_{Nj} e^{imk\hat{\mathbf{k}}_N \cdot \mathbf{r}_\beta} \tag{34}$$

and these are related to the electric field like this

$$\mathbf{F}(\mathbf{r}) = \mathbf{E}(\mathbf{r})(1 + \frac{4\pi}{3}\chi)$$

so

$$\frac{\mathbf{F}(\mathbf{r})}{(1 + \frac{4\pi}{3}\chi)} = \mathbf{E}(\mathbf{r})$$

and we have our electric field.

This is what the code is supposed to do.

1.2 Self Term

Equation (5) can be written as a sum where the infinitesimal volume d^3r' is now a finite volume d_ν^3:

$$\begin{aligned} F_i(\mathbf{r}_\mu) &= E_i^{in}(\mathbf{r}_\mu) + \sum_{\nu \neq \mu} d_\nu^3 G_{ij}(\mathbf{r}_{\mu\nu}) W F_j(\mathbf{r}'_\nu) + I_i(\mathbf{r}_\mu) \\ &= E_{\mu,i}^{in} + W \sum_{\nu \neq \mu} d_\nu^3 G_{\mu i \nu j} F_{\nu j} + I_{\mu i} \end{aligned} \tag{35}$$

Here $I_{\mu i}$ is the self term, and Greek indices run and sum over dipole cell number and the Latin indices run and sum over vector components. Also, $\mathbf{r}_\mu$ is at the center of cell number μ. Of course, this only works well if d_μ^3 is small. Experience shows that $|m|\, kd < 1$ should be used, where m is the complex refractive index of the homogenous particle.

The Green's function is discretized as

$$G_{\mu i \nu j} = \exp(ikR_{\mu\nu}) \left[\frac{k^2}{R_{\mu\nu}} \left(\delta_{ij} - \widehat{R_{\mu\nu i}} \widehat{R_{\mu\nu j}} \right) + \left(\frac{ik}{R_{\mu\nu}^2} - \frac{1}{R_{\mu\nu}^3} \right) \left(\delta_{ij} - 3\widehat{R_{\mu\nu i}} \widehat{R_{\mu\nu j}} \right) \right] \tag{36}$$

where $\mathbf{R}_{\mu\nu} = \mathbf{r}_\mu - \mathbf{r}_\nu$. This equation is very similar to that used by Goedecke and O'Brien.[**?**]

But a problem occurs when the summation index ν is equal to μ : Terms with $R_{\mu\mu}$ in the denominator would diverge (blow up to infinity). Thus in equation (50) these terms have been separated. Because such a term results from the action of the cell field on itself, it is known as the self-term. The self-term results from letting $\mathbf{r} = \mathbf{r}_\mu$, and $\mathbf{r}' = \mathbf{r}_\mu + \boldsymbol{\xi}$, in equation (4) , and taking $\chi(\mathbf{r}')\mathbf{F}_j(\mathbf{r}') = \chi(\mathbf{r}_\mu)\mathbf{F}_j(\mathbf{r}_\mu)$. One gets

$$I_{\mu,i} = \left[\int_\square d^3\xi G_{ij}(\boldsymbol{\xi}) \right] W F_j(\mathbf{r}_\mu) \tag{37}$$

The $\square$ indicates that the integral is over the small dipole cell, of volume d_μ^3. The integral in brackets in equation (52) can be written as

$$\int_\square d^3\xi G_{ij}(\boldsymbol{\xi}) = \int_\square d^3\xi e^{ik\xi} \left[\frac{k^2}{\xi} \left(\delta_{ij} - \hat{\xi}_i \hat{\xi}_j \right) + \left(\frac{ik}{\xi^2} - \frac{1}{\xi^3} \right) \left(\delta_{ij} - 3\hat{\xi}_i \hat{\xi}_j \right) \right] \tag{38}$$

Employing the identity

$$\int_{\square} d\Omega_{\xi} \hat{\xi}_i \hat{\xi}_j = \delta_{ij} \frac{1}{3} \int_{\square} d\Omega_{\xi} \tag{39}$$

the last term vanishes due to symmetry of cubical cells. Also, the remaining terms can be combined to yield

$$\int_{\square} d^3\xi G_{ij}\left(\boldsymbol{\xi}\right) = \delta_{ij} \frac{2k^2}{3} \int_{\square} d^3\xi \frac{k^2 e^{ik\xi}}{\xi} \tag{40}$$

A series expansion of the integrand on the right hand side yields

$$\frac{\exp(ikx)}{x} = \left[\frac{1}{x} + ik - \frac{1}{2}k^2 x - \frac{1}{6}ik^3 x^2 + \frac{1}{24}k^4 x^3 + Ox^4\right] \tag{41}$$

which can be substituted into the previous expression to yield

$$\begin{aligned} \int_{\square} d^3\xi G_{ij}\left(\boldsymbol{\xi}\right) &= \delta_{ij} \frac{2k^2}{3} \int_{\square} d^3\xi \left(\frac{1}{\xi} + ik - \frac{1}{2}k^2\xi - \frac{1}{6}ik^3\xi^2 + \frac{1}{24}k^4\xi^3 + O\left(\xi^4\right)\right) \\ &\equiv \delta_{ij} \frac{4\pi}{3} \Gamma \end{aligned} \tag{42}$$

where this equation defines Γ as

$$\Gamma = \left((ka)^2 + \frac{2}{3}i\left(ka\right)^3 - \frac{1}{4}\left(ka\right)^4 - \frac{1}{15}i\left(ka\right)^5 + O\left(ka\right)^6\right) \tag{43}$$

and the integral has been done by using an equivalent volume sphere with radius a_μ

$$a_\mu = d_\mu \left(\frac{3}{4\pi}\right)^{\frac{1}{3}} \tag{44}$$

thus

$$\begin{aligned} \Gamma_\mu &= \left(\frac{3}{4\pi}\right)^{\frac{2}{3}} \left(kd_\mu\right)^2 + \left(\frac{i}{2\pi}\right)\left(kd_\mu\right)^3 - \frac{1}{4}\left(\frac{3}{4\pi}\right)^{\frac{4}{3}}\left(kd_\mu\right)^4 \\ &\quad -\frac{1}{15}i\left(\frac{3}{4\pi}\right)^{\frac{5}{3}}\left(kd_\mu\right)^5 + O\left(\left(kd_\mu\right)^6\right) \end{aligned} \tag{45}$$

The expression for $I_{\mu i}$ can then be written as

$$I_{\mu i} = \delta_{ij} \frac{4\pi}{3} W \Gamma_\mu F_{\mu j} = \frac{4\pi}{3} W \Gamma_\mu F_{\mu i} \tag{46}$$

The first two terms in Γ_μ were used by Goedecke and O'Brien in their formulation of the DGF scattering code [**?**]. Draine and Goodman obtained a somewhat different expression for Γ_μ for placement of the dipole cells on a cubic lattice[**?**], i.e. the coefficients of the various powers of kd_μ are different than in equation(60). However, for ease in comparison with the DGF method,

the form given by Goedecke and O'Brien is used here. The corrections of order $(kd_\mu)^4$and higher are insignificant; and even the term in $(kd_\mu)^2$ is not important if $kd_\mu \ll 1$. But, as shown by Goedecke and O'Brien, the lowest order imaginary term proportional to $(kd_\mu)^3$ is essential for agreement with the optical theorem, and this term is the same in the Draine and Goodman expression.

1.3 Initialized variables

The code initializes variables in lines 51-86. ForTran requires variables to be declared like in C++. It uses parenthesis to indicate an array.

We start with

the maximum number of possible dipole cells	$NMAX$
Number of k-vectors	$KNMAX$

	$IPVT(3*KNMAX)$
	$z\,(3*KNMAX)$
	$rcond$
	$NUSE$
	I
	J
	$mcount$
	$kcount$

	N
	M

$DEG = PI/180.0$
$CI = (0.0, 1.0)$
$iseed = 234564$

2 Main Program

The program defines many variables at the start. After defining π and i in line 86, it defines the particle permittivity ϵ in line 107, the complex index of refraction mm in line 108, and the complex suseptability χ in line 109.

It inputs the positions and weights for our dipoles in lines 110 to 116.

It then find the wave number, k in line 119 and it rotates the direction of the incident electric field into the position we asked for in vgfin in lines 125-135.

It then calculates the W factor (137)

$$W\,(\nu) = \frac{\chi}{1 + \frac{4\pi}{3}\chi}$$

and the incident feild (147)

$$E_o\,(r) = e^{-ik\mathbf{r}\cdot\hat{\mathbf{k}}}$$

for every r where we have placed a dipole.

The program then calls a subroutine to bring in our direction angles for each of the $k - vectors$. (152)

The program then calles kvector3 to turn the k-vector direction angles into the components of the $\hat{k}$ vectors.

The program then starts the monte carlo loop. In this loop it calclates where

$$\Psi_{\beta N} = e^{imk\hat{\mathbf{k}}_N\cdot\mathbf{r}_\beta} \tag{47}$$

$$\psi = e^{(i*k*khatN.R(b))}$$

equation 183

We want to find the a_{Nj} in

$$\tilde{F}_{\beta j} = \sum_{N=1}^{N_k} a_{Nj} \Psi_{\beta N} \tag{48}$$

and use this to find our E field

$$\frac{\mathbf{F}(\mathbf{r})}{(1 + \frac{4\pi}{3}\chi)} = \mathbf{E}(\mathbf{r})$$

The code caluclates

$$T_{\alpha i N j} = \sum_{\beta} \left(1_{\alpha i \beta j} - G_{\alpha i \beta j} W_{\beta}\right) \Psi_{\beta N}$$

$$T1_{(a,i,N,j)} = T1_{(a,i,N,j)} + (dd_{(a,i,b,j)} - d^3_{(b)} * W * GG)\psi$$

$$T1_{(a,i,N,j)} = T1_{(a,i,N,j)} + (dd_{(a,i,b,j)} - d^3_{(b)} * W * GG_{(R,k,dtemp,EPS,a,i,b,j)}) e^{(i*k*khatN.R(b))}$$

which is equation 185 and happens between lines (166) and (181).
@@@I don't know what $d\,(b)$ is yet.
Now it calculates Y (191)

$$Y_{Nj} = \sum_{\alpha} \sum_{i} T^*_{\alpha i N j} E^o_{\alpha i}$$

and then (199)

$$H_{MlNj} = \sum_{\alpha} \sum_{i} T^*_{\alpha i M l} T_{\alpha i N j}$$

Then it does a matrix solve. It first must reshape our multidimensional matricies into two-dimensional matricies because that is what the inversion routine can do.

So Y_{Nj} is turned into $bb\,(m)$ and H_{MlNj} is turned into $aa(m, mp)$

It then does something with ipvt and z that I need to figure out @@@@@@

The call to cgeco Factors a COMPLEX matrix by Gaussian elimination and estimates the condition of the matrix.

The call to Solves the COMPLEX system A*X=B or CTRANS(A)*X=B using the factors computed by CGECO or CGEFA. The verablee bb is the solution.

The result should be the a_{Nj} values which we then use to calculate

$$\tilde{F}_{\beta j} = \sum_{N=1}^{N_k} a_{Nj} \Psi_{\beta N} \tag{49}$$

and then

$$\mathbf{E}(\mathbf{r}) = \frac{\mathbf{F}(\mathbf{r})}{(1 + \frac{4\pi}{3}\chi)}$$

3 Subroutines

3.1 Subroutine getkvectors(kth,kph,NK,KFILE,ERR,ERRlast,mcount,kcount)

subroutine to read in the kvectkors from the file KFILE
subroutine kvectors(NTH,khatN,count) *
complex Function GAM(d,k,EPS) *
complex function CPSI(R,KhatN,k,mm,N,b) *

3.2 complex Function Wcalc(X,d,k,EPS)

this fucntion calcualtes the W-factor from the dissertation equation 39 and 141.

$$W(\nu) = \frac{\chi}{1 + \frac{4\pi}{3}\chi}$$

where χ is the complex suseptibility.
subroutine Gcalc(R,k,Gmn,d,EPS,m,n) *
real function delta(alpha,beta) *
real function dd(alpha,i,beta,k) *
subroutine ROT(RRR, alpha, beta, gamma) *
subroutine MV(M,V,U) subroutine to multiply a 3x3 matrix by a vector with three components

3.3 The digitized Green's function

Equation (4) can be written as a sum where the infinitesimal volume d^3r' is now a finite volume d_ν^3:

$$\begin{aligned} F_i(\mathbf{r}_\mu) &= E_i^{in}(\mathbf{r}_\mu) + \sum_{\nu \neq \mu} d_\nu^3 G_{ij}(\mathbf{r}_{\mu\nu}) W F_j(\mathbf{r}'_\nu) + I_i(\mathbf{r}_\mu) \qquad (50) \\ &= E_{\mu,i}^{in} + W \sum_{\nu \neq \mu} d_\nu^3 G_{\mu i \nu j} F_{\nu j} + I_{\mu i} \end{aligned}$$

Here $I_{\mu i}$ is the self term, and Greek indices run and sum over dipole cell number and the Latin indices run and sum over vector components. Also, $\mathbf{r}_\mu$ is at the center of cell number μ. Equation (50) only approximates equation (4) well if d_μ^3 is small. Experience shows that $|m|\, kd < 1$ should be used, where m is the complex refractive index of the homogenous particle.

The Green's function is discretized as

$$G_{\mu i \nu j} = \exp(ikR_{\mu\nu}) \left[\frac{k^2}{R_{\mu\nu}} \left(\delta_{ij} - \widehat{R_{\mu\nu i}} \widehat{R_{\mu\nu j}} \right) + \left(\frac{ik}{R_{\mu\nu}^2} - \frac{1}{R_{\mu\nu}^3} \right) \left(\delta_{ij} - 3\widehat{R_{\mu\nu i}} \widehat{R_{\mu\nu j}} \right) \right] \qquad (51)$$

where $\mathbf{R}_{\mu\nu} = \mathbf{r}_\mu - \mathbf{r}_\nu$. This equation is very similar to that used by Goedecke and O'Brien.[**?**]

3.3.1 Self-Term

A problem occurs when the summation index ν is equal to μ : Terms with $R_{\mu\mu}$ in the denominator would diverge. Thus in equation (50) these terms have been separated. Because such a term results from the action of the cell field on itself, it is known as the self-term. The self-term results from letting $\mathbf{r} = \mathbf{r}_\mu$, and $\mathbf{r}' = \mathbf{r}_\mu + \boldsymbol{\xi}$, in equation (4) , and taking $\chi(\mathbf{r}')\,\mathbf{F}_j(\mathbf{r}') = \chi(\mathbf{r}_\mu)\,\mathbf{F}_j(\mathbf{r}_\mu)$. One gets

$$I_{\mu,i} = \left[\int_\square d^3\xi G_{ij}(\boldsymbol{\xi})\right] WF_j(\mathbf{r}_\mu) \tag{52}$$

The $\square$ indicates that the integral is over the small dipole cell, of volume d_μ^3. The integral in brackets in equation (52) can be written as

$$\int_\square d^3\xi G_{ij}(\boldsymbol{\xi}) = \int_\square d^3\xi e^{ik\xi}\left[\frac{k^2}{\xi}\left(\delta_{ij} - \hat{\xi}_i\hat{\xi}_j\right) + \left(\frac{ik}{\xi^2} - \frac{1}{\xi^3}\right)\left(\delta_{ij} - 3\hat{\xi}_i\hat{\xi}_j\right)\right] \tag{53}$$

Employing the identity

$$\int_\square d\Omega_\xi \hat{\xi}_i\hat{\xi}_j = \delta_{ij}\frac{1}{3}\int_\square d\Omega_\xi \tag{54}$$

the last term vanishes due to symmetry of cubical cells. Also, the remaining terms can be combined to yield

$$\int_\square d^3\xi G_{ij}(\boldsymbol{\xi}) = \delta_{ij}\frac{2k^2}{3}\int_\square d^3\xi \frac{k^2 e^{ik\xi}}{\xi} \tag{55}$$

A series expansion of the integrand on the right hand side yields

$$\frac{\exp(ikx)}{x} = \left[\frac{1}{x} + ik - \frac{1}{2}k^2x - \frac{1}{6}ik^3x^2 + \frac{1}{24}k^4x^3 + Ox^4\right] \tag{56}$$

which can be substituted into the previous expression to yield

$$\begin{aligned}\int_\square d^3\xi G_{ij}(\boldsymbol{\xi}) &= \delta_{ij}\frac{2k^2}{3}\int_\square d^3\xi\left(\frac{1}{\xi} + ik - \frac{1}{2}k^2\xi - \frac{1}{6}ik^3\xi^2 + \frac{1}{24}k^4\xi^3 + O\left(\xi^4\right)\right)\\ &\equiv \delta_{ij}\frac{4\pi}{3}\Gamma\end{aligned} \tag{57}$$

where this equation defines Γ as

$$\Gamma = \left((ka)^2 + \frac{2}{3}i(ka)^3 - \frac{1}{4}(ka)^4 - \frac{1}{15}i(ka)^5 + O(ka)^6\right) \tag{58}$$

and the integral has been done by using an equivalent volume sphere with radius a_μ

$$a_\mu = d_\mu\left(\frac{3}{4\pi}\right)^{\frac{1}{3}} \tag{59}$$

thus

$$\Gamma_\mu = \left(\frac{3}{4\pi}\right)^{\frac{2}{3}}(kd_\mu)^2 + \left(\frac{i}{2\pi}\right)(kd_\mu)^3 - \frac{1}{4}\left(\frac{3}{4\pi}\right)^{\frac{4}{3}}(kd_\mu)^4 - \frac{1}{15}i\left(\frac{3}{4\pi}\right)^{\frac{5}{3}}(kd_\mu)^5 + O\left((kd_\mu)^6\right) \quad (60)$$

The expression for $I_{\mu i}$ can then be written as

$$I_{\mu i} = \delta_{ij}\frac{4\pi}{3}W\Gamma_\mu F_{\mu j} = \frac{4\pi}{3}W\Gamma_\mu F_{\mu i} \quad (61)$$

The first two terms in Γ_μ were used by Goedecke and O'Brien in their formulation of the DGF scattering code [**?**]. Draine and Goodman obtained a somewhat different expression for Γ_μ for placement of the dipole cells on a cubic lattice[**?**], i.e. the coefficients of the various powers of kd_μ are different than in equation(60). However, for ease in comparison with the DGF method, the form given by Goedecke and O'Brien is used here. The corrections of order $(kd_\mu)^4$and higher are insignificant; and even the term in $(kd_\mu)^2$ is not important if $kd_\mu \ll 1$. But, as shown by Goedecke and O'Brien, the lowest order imaginary term proportional to $(kd_\mu)^3$ is essential for agreement with the optical theorem, and this term is the same in the Draine and Goodman expression.

The code that does this is the subroutine GG

3.4 In Order in the Code

51-78 Declare variables

80 Set inputfile (from vgfin.f), the output file name, and kfile (from vgfkv.f)

82-83 Declare function types. We will use several functions in this code that are specific to the code. They are declared here.

87-88 Define some constants

89-98 Interact with the user to get input data

99-116 Open the input file (from vgfin.f) and read in NUSE, Wave, Alpha, Beta, Gamma, Psi, RAD, Er, EI, TD and the cell positions. Along the way calculate χ, ε, and m.

117-135 Make the incoming plane wave and then rotate it into the right position. This starts with angles α, β, and γ and converts from degrees to radians. The the function Rot is used to calculate a rotation matrix. This function calculates the Euler rotation matrix where the three rotation angles are alpha, a rotation about the z-axis, beta, a rotation about the new y-axis,

and gamma, a rotation about the new z-axis.

$$RRR = \begin{pmatrix} \cos\alpha\cos\beta\cos\gamma - \sin\alpha\sin\gamma & \cos\alpha\cos\beta\cos\gamma - \cos\alpha\sin\gamma & \sin\beta\cos\gamma \\ -\cos\alpha\cos\beta\sin\gamma - \sin\alpha\cos\gamma & -\sin\alpha\cos\beta\sin\gamma + \cos\alpha\cos\gamma & \sin\beta\sin\gamma \\ \cos\alpha\sin\beta & \sin\alpha\sin\beta & \cos\beta \end{pmatrix}$$

we will start with our input direction being in the z-direction

$$V_k = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}$$

so our new direction for our incoming wave in the particle frame is

$$Khat = RRR * V$$

where the function MV is used to do the multiply. But then we want the E-vector to be in the $x - y$ plane in the lab frame (can't remember why). So take

$$V_E = \begin{pmatrix} \cos\psi \\ \sin\psi \\ 0 \end{pmatrix}$$

then rotate into our particle frame

$$E_{Ohat} = RRR * V$$

and use MV again to do the multiply.

137 Calculate the W factor using function Wcalc

$$W(\nu) = \frac{\chi}{1 + \frac{4\pi}{3}\chi}$$

138-148 Form the incoming field. This will be of the form

$$\mathbf{E}(\mathbf{r}, t) = E_o \exp(i\mathbf{r} \cdot \mathbf{k}) \exp(-i\omega t)$$

And we want to know the value of the field at every cell. The code makes the $\mathbf{r} \cdot \mathbf{k}$ in a loop from 140-142. It has to do this for each cell. So there is an outside loop from 138 to 148 that loops over cells and the r components will be different for every cell as we calculated in vgfin.f. The $\mathbf{r} \cdot \mathbf{k}$ is then multiplied by i in line 143 and then put into an exponent in line 144 and finally the efield components are assembled in a small loop in lines 145 to 147.

151-154 Now go and get the k-vectors that we built in vgfkv.f. These will be used to form the outgoing scattered field.

156-242 is the Monty Carlo loop that finds the outgoing scattered field. It caucluates the a_{Nj} so later we can form

$$\tilde{F}_{\beta j} = \sum_{N=1}^{N_k} a_{Nj} \Psi_{\beta N}$$

and then

$$\mathbf{E}(\mathbf{r}) = \frac{\mathbf{F}(\mathbf{r})}{(1 + \frac{4\pi}{3}\chi)}$$

which is what we want as our answer.

The loop starts with finding $\Psi_{\beta N}$

$$\Psi_{\beta N} = e^{imk\hat{\mathbf{k}}_N \cdot \mathbf{r}_\beta}$$

$$\psi = e^{(i*k*khatN.R(b))}$$

and this is done with a call to the function CPHI.

Then it starts to calculate

$$ERR = |\Psi_{\beta N}|^2$$

This will be our optimization test. In line 248 we check to see if $ERR > ERR0$ The $ERR0$ was something we asked the user to input at the start. If $ERR < ERR0$ then we are done with one itteration. The original inputs worked. So the code jumps down to the else clause in line 275 and it calles Ecalc to calcuate the scattered efield
